

EUROPEAN INTERNET

Behind and Moving Slowly

Dai Davies, DANTE's General Manager, reports that while the European Internet is in a relatively sorry state, initiatives to improve the situation are well-advanced.

The European Internet is currently struggling with a number of issues the North American Internet has just dealt with. On 30 April 1995, the National Science Foundation backbone network NSFnet ceased to exist. Last year a transition process started to replace it with a new architecture, in part restricted to research purposes and in part for commercial usage. The NSFnet backbone was set up nine years ago to interconnect six super-computer centres, and started operating at 56 kilobit/second (Kbps). Just before its "retirement" the network operated at a speed of 45 Megabit/second (Mbps). The new architecture allows NSF to focus (again) on its primary mission of promoting scientific research and development.

US - A Neat Solution

The NSFnet's bandwidth – which was provided to the research community under favourable commercial conditions – was increasingly being re-sold by them to commercial organizations. The big telecoms operators argued – and rightly so – that there was no way they could compete for commercial customers in a subsidised market.

The US response to this problem was twofold. For routine services (up to 45 Mbps), they shifted from paying for the network to subsidising the users and at the same time encouraging the creation of a true Internet market. This was achieved by defining a technical structure for the market which favoured pan-US operators. This way competition between the large network operators will let the market do its work, and connecting networks will be able to obtain Internet access at a reasonable price and without the commercial distortions to which the Internet market is prone. Secondly, in the new structure a very high-speed Backbone Network Service (vBNS) is being established at 155 MBps, with use restricted to research organizations.

The new set-up features four Network Access Points (NAPs) – neutral interconnection points where network providers interconnect with other providers – as well as a number of national Network Service Providers (NSPs) to carry national traffic at slower speeds. NAPs are not financed directly by NSF. Instead, NSF funds regional network attachments to NSPs, but only to those who are present at all the NAPs. This encourages scale and favours the large operators who can exploit economies of scale. This support will decline to zero over four years. NAPs interconnect the vBNS and other backbone networks, both domestic and foreign. Thus the NSF has neatly solved the problem of resale and cross-subsidy, created a market of some scale for Internet services, and preserved its role as the provider of advanced technology networking to the academic community in the US. The key NSPs are MCI, US Sprint and ANS, the original operator of the NSFnet backbone. The major players in the US telecommunications market have emerged as the key players in the US Internet.

University of Trondheim
Department of Physics - Department of Industrial Chemistry

Postdoctoral Position

A postdoctoral position for a duration of two years is available at the University of Trondheim, NTH. The position is financed by the Norwegian Research Council (NFR) and is part of a Strategic University Programme in Surface Science. The programme is a joint venture between the Departments of Physics and of Industrial Chemistry, with emphasis on problems relevant to catalysis. The successful applicant must possess a Ph.D., and must document strong scientific qualifications in experimental surface science. A background in experimental studies of metallic systems is preferred. The major experimental techniques include XPS, UPS, STM, ellipsometry, and IR-spectroscopy. UHV experience as well as experience in one or more of the experimental techniques are required.

The salary is at present approximately NOK 265.900,- per year. Questions regarding the position may be directed to A. Borg (borga@phys.unit.no), A. Holmen (anders.holmen@kjemi.sintef.no), O. Hunderi (hunderi@phys.unit.no), or S. Raaen (sraaen@phys.unit.no). Applications should be mailed to Prof. S. Raaen, Department of Physics, NTH, N-7034 Trondheim, Norway. Applicants should arrange to have two letters of recommendations sent to the above address. Applications are welcome before **December 15, 1995**.

NEW!

A Chronicle of Pre-Telescopic Astronomy

BARRY HETHERINGTON, County Durham, UK

Astronomy, the oldest of the sciences, has a history which goes back thousands of years. Civilizations throughout the world recorded events which they observed, including the behaviour of comets, meteors and stars. These observations contain a wealth of information which is of great importance and interest to the modern-day astronomer.

- Presents a record of astronomical discoveries, events, and biographical details of astronomers from the earliest times to the year 1609AD
- Entries are chronologically arranged and copiously referenced
- Index of 1000 names, and an extensive subject index
- All entries are referenced for readers' further investigations

0471959421 approx 304pp due January 1996 approx £50.00

NEW!

Astronomical Observations of Ancient East Asia

FRANCIS R. STEPHENSON, University of Durham, UK, ZHENTAO XU, Academia Sinica, China and YAOTIAO TIANG, Nanjing University, China

A unique compilation of a wide variety of astronomical observations from East Asia which are of special value today and play a major role in modern scientific studies of eclipses of the Sun and Moon, comets, exploding stars, and phenomena such as the aurora borealis and meteor showers.

- Full translations of detailed records with dates on the Julian Calendar appear in tabular form
- Chapter devoted to the most ancient astronomical records in East Asian history 1500-1050BC
- The first time this detailed information has been published outside East Asia and presented in an easily readable form

Wiley Praxis Series in Astronomy and Astrophysics
0471960179 approx 300pp due November 1995 approx £40.00

NEW!

The New Russian Space Programme From Competition to Collaboration

BRIAN HARVEY, Dublin, Ireland

The first book to take advantage of the rich stream of glasnost material to come out of the former USSR since 1988. The real purpose of many mysterious missions, flights and events has now become clear. Thanks to glasnost, the record can be set straight and truth can replace speculation.

- Explains the consequences of the collapse of the USSR and its effects on the space programme, as we enter a new era of international collaboration in space ventures
- Pays balanced attention to political, engineering, design, personality and human considerations

Wiley Praxis Series in Astronomy and Astrophysics
0471960144 approx 400pp due December 1995 approx £24.95

Cheques made payable to 'John Wiley & Sons Ltd', marked for the attention of Nicky Douglas. For credit card orders phone +44 (0)1243 770392 or fax +44 (0)1243 770154. All prices are correct at time of going to press. Please add £2.00 to cover postage. Save money - order more than one book and postage is FREE! All books are available from your bookseller.

Europe - Some Do Better

The problem in Europe is similar, but unfortunately the US solution does not easily apply. The situation is complicated by political and regulatory issues which will come to a head in 1998 when the telecoms market in Europe is liberalised.

In Europe, the Internet was also created by the research community. The national university networks in Europe have worked together since the mid-1980s to establish a rational cross-border networking infrastructure for their international traffic. Cross-border connections in Europe are very expensive, especially high-speed connections which are difficult to obtain from the national (monopoly) Public Network Providers. The result of a collaboration between national networks is EuropaNET (launched in 1992) which is a pan-European backbone network, based on 2 Mbps links, interconnecting national research networks in 18 countries and offering interconnections with the rest of the global Internet. At the moment, customers are connected at a maximum speed of 6 Mbps. EuropaNET is managed by DANTE, a company set up by the national networks to centralise the organization of cross-border network services for their purposes – a mandate similar to that of the NSF in the US. A major difference between DANTE and NSF is that DANTE does not channel pan-European funds like NSF does. Funding always has to be organized on an *ad hoc* (and service-related) basis, which makes the setting out of a long-term strategy very difficult.

During the past two years, heated debates have taken place between small commercial Internet providers and the research networks, in particular DANTE representing EuropaNET. Some commercial Internet providers in Europe insist that all Internet networks should inter-connect to each other without charge for the sake of the "spirit of the Internet". DANTE, having invested significant amounts of money in the establishment, maintenance and continuous upgrading of EuropaNET, argues that whoever uses the network should pay for it. It is hardly fair that a network like NORDUnet, which itself interconnects five national research networks in Scandinavia, should pay for a connection while a much smaller, commercial network operating within one country, would get a free connection. More importantly, the acceptance of this point of view would make the whole collaborative model, and as a result the European backbone, collapse, as each network could claim to be offering connectivity to itself in return for a connection to the backbone. While the spirit of the Internet may have substance in the US, under the European commercial circumstances it is no more than an easy and opportunistic argument which serves (the economic interests of) some better than others.

A Proposed High-Speed Network

In October 1994 the Acceptable Use Policy on EuropaNET was removed and from October 1995 on the network became fully open for commercial organizations. This way Europe's research community has created a high-quality infrastructure which can now be "handed over" for

DANTE is a not-for-profit company, set up in 1993 by a number of national university networks in Europe, to organize international network services for the European research community. EuropaNET, an international backbone network that connects the national research networks to each other and to the global Internet, is DANTE's main service. DANTE also organizes pan-European networking projects and is involved in the TEN-34 project which aims to establish a high-speed pan-European backbone network for research.

general commercial exploitation. The difference between Europe and the States is only ... 43 Mbps ... European researchers also need a high-speed network infrastructure. Since 1993, the university networks have set up a series of collaborations in an effort to speed up the creation of a pan-European high-speed network. Six of them have already established a national high-speed backbone and are now urgently seeking ways of getting a complementary European backbone in place as well.

Their latest initiative is TEN-34, a proposal backed by a consortium formulated in response to the Call for Proposals of the European Union's 4th Framework programme. In the Consortium, 18 networks work together with DANTE as the co-ordinating partner. The TEN-34 proposal consists of two elements: a detailed implementation plan for the speedy setting up of a 34 Mbps Internet Protocol (IP) backbone in combination with the development of an international high-speed asynchronous transfer mode (ATM) test network. Like the vBNS, this network will be restricted to academic use. The difference between Europe and the United States would then be only ... 121 Mbps.

ATM - The Future ?

ATM offers two potential benefits over current switching and transmission technology. Firstly, it is capable of providing a more flexible division of bandwidth enabling both synchronous and asynchronous connections to be provided on the same link. Secondly, as the switching technology develops it will allow dynamic allocation of bandwidth to meet the requirements of individual applications thereby permitting greater flexibility and more efficient use of network capacity.

There are three great challenges to ATM. Firstly, there is the **commercial** challenge. A great success of Internet is fixed access pricing. It encourages some less than optimum usage of network resources and actually imposes Quality of Service by rationing rather than by price. But predictable bills are popular. If ATM services are expensive, never mind the fact that they can be managed economically, they will be unpopular. ATM represents a potential for future telecommunications services but will only succeed if the real cost-reductions offered by technology are actually made available to the user. The market for ATM needs to be driven by increasing supply through low prices rather than by rationing demand through high prices. Users will stick to the simple Internet if demand is to be rationed.

The second major issue is the lack of **maturity** in the technology. Although the basic ideas of cell relay are well understood, the control mechanisms that take a technology to the point where it can be used as a real service still require development effort. This lack of maturity is reflected in the European PNO ATM pilot where the facsimile machine was used as the signalling system. Facsimile is one of the few success stories of PNO standardisation efforts, but it was not really specified as a signalling system for advanced network technology. It is a measure of DANTE's belief in the need for this process to succeed that we are investing effort in defining an ATM test network. It is also a measure of our scepticism that for it to succeed we shall need to invest such effort.

Thirdly, there is the **standardisation** challenge. Large-scale international standardization efforts do not have a good track record of success in creating international products. By contrast, where the market has been dominated initially by a single supplier who has been able to impose a *de facto* solution, standardization has proceeded quite quickly. The standardization process for ATM has cut some corners. It will remain to be seen whether it will produce reliable products from a variety of vendors.

ATM represents a major new technology. It has the potential to meet the emerging requirements of the generation of multi-media applications that are under development. Within the networking research community, there is considerable interest in its usage. However, ATM will only succeed if it learns the hard lessons demonstrated by earlier networking technologies.

Compared to the US, the European Internet is in a rather sad state. The good news is that initiatives to improve the situation are well-advanced. However, some serious obstacles remain such as the telecoms operators' unwillingness to deliver, commercial unmanageability of the Internet, the non-existence of a pan-European funding body dedicated to the long-term development of an advanced network infrastructure, and technical and commercial uncertainties with respect to ATM. The next two years will be decisive for the future of European networking; as organization set up to centralise all European networking efforts for the research community, DANTE is in an ideal position to make the most of it.

DANTE's EuropaNET in October 1995
